## 1 HJB equations

### Incumbent

HJB equation:

$$\begin{aligned} rV(q, m) = & \tilde{\pi}q + \nu z_E(q, m)V_m(q, m) - gqV_q(q, m) \\ & + \max_{\ell \geq 0, x \in \{0,1\}} \left\{ -w(q, m; x)\ell + x\nu\ell V_m(q, m) \right. \\ & \left. + \ell\phi(\ell + L^E(q, m)) \left[ V((1 + \lambda)q, 0) - V(q, m) \right] \right\} \end{aligned}$$

Boundary conditions:

$$\begin{aligned} V(0, m) &= 0 \\ \forall m \geq M(q) : V_m(q, m) &= 0 \end{aligned}$$

Solution method: Moll's approach. Guess a terminal condition  $V(q, m, T)$  and integrate the HJB backwards in time until convergence to the stationary value. Depends on future becoming insignificant as we go to infinite past, which holds in models with discounting. So it should work.

How to ensure that boundary conditions are satisfied? Seems like one easy way is to make sure that the initial guess satisfies them. Based on the algorithm, the guess  $L^E(q, m)$  becomes constant past  $m = M^*(q)$ , which is one of the objects we are iterating to find a fixed point over. Since  $q$  drifts downwards (and jumps in  $q$  set  $m = 0$  again), and finally since  $M^*(q)$  is increasing (a guess, but I'm pretty sure will hold in equilibrium), this implies that  $V(q, m)$  is constant for  $m \geq M^*(q)$ . So we simply impose this guess, plus  $V(0, m) = 0$ , on our initial guess, and we solve the time-dependent PDE,

$$\begin{aligned}
V_t(q, m, t) = & -rV(q, m, t) - gqV_q(q, m, t) \\
& + \max_{\ell} \left\{ -w(q, m; x)\ell + x\nu\ell V_m(q, m, t) \right. \\
& \left. + \ell\phi(\ell + L^E(q, m)) [V((1 + \lambda)q, 0, t) - V(q, m, t)] \right\}
\end{aligned}$$

## Worker not bound by non-compete

HJB equation:

$$\begin{aligned}
W(q, m) = & -gqW_q(q, m) \\
& + \max_{\ell} \left\{ -w(q, m; x)\ell \right. \\
& \left. + \ell\phi(L^I(q, m) + L^E(q, m)) [V((1 + \lambda)q, 0) - W(q, m)] \right\}
\end{aligned}$$

Boundary conditions:

## Finite difference

### Incumbent

#### Explicit method

Define  $\Delta_t$

#### 1.0.1 Semi-implicit method

In order to make this work, need to be smart about what grid points we use for  $q$ . Essentially, need it to be possible to compute  $V^+$  without explicit reference to  $q$ , only to the index  $i_q$ . This can be achieved by having the points on the grid log-spaced; specifically,  $q_{i+1} = q_i * (1 + \lambda)^{1/m}$  for some  $m \geq 1$ . Set  $m > 1$  to make the grid finer.

Discretization:

$$\begin{aligned}
\frac{V_{i,j}^{n+1} - V_{i,j}^n}{\Delta_t} + (\rho - g)V_{i,j}^{n+1} = & f_{i,j}^n + \xi_{i,j}^n V_{i,j}^{n+1} + \eta_{i,j} V_{i-1,j}^{n+1} + \gamma_{i,j} V_{i,j+1}^{n+1} \\
& + \sigma_{i,j} (V^{n+1})_{i,j}^+
\end{aligned}$$

with

$$\begin{aligned}
f_{i,j}^n &= \pi_{i,j} + x_{i,j}^n(-\bar{w}z_{i,j}^n) + (1 - x_{i,j}^n)(-w_{i,j}z_{i,j}^n) \\
\xi_{i,j}^n &= -gq/\Delta_i^q - (\chi_I z_{i,j}^n + \chi_E z_{i,j}^E)\phi(z_{i,j}^n + z_{i,j}^E)h(q_i) \\
\eta_{i,j}^n &= gq/\Delta_i^q \\
\gamma_{i,j}^n &= \nu(z_{i,j}^E + (1 - x_{i,j}^n)z_{i,j}^n)/\Delta_i^m \\
\sigma_{i,j}^n &= \chi_I z_{i,j}^n\phi(z_{i,j}^n + z_{i,j}^E)h(q_i)
\end{aligned}$$

Further, we compute  $(V^{n+1})_{i,j}^+$  as follows:

$$(V^{n+1})_{i,j}^+ = \begin{cases} V_{i+m,0}^{n+1} & i < I - (m-1) \\ V_{i,0}^{n+1} + \frac{\lambda}{(1+\lambda)^{1/m}-1} (V_{i+1,0}^{n+1} - V_{i,0}^{n+1}) & I - (m-1) \leq i < I \\ V_{i,0}^{n+1} + \frac{\lambda}{1-(1+\lambda)^{-1/m}} (V_{i,0}^{n+1} - V_{i-1,0}^{n+1}) & i = I \end{cases}$$

Grouping like terms, have the expression

$$\begin{aligned}
(V^{n+1})_{i,j}^+ &= \mathbb{1}_{\{i < I-(m-1)\}} V_{i+m,0}^{n+1} \\
&+ \mathbb{1}_{\{I-(m-1) \leq i < I\}} \left( \left(1 - \frac{\lambda}{(1+\lambda)^{1/m}-1}\right) V_{i,0}^{n+1} + \frac{\lambda}{(1+\lambda)^{1/m}-1} V_{i+1,0}^{n+1} \right) \\
&+ \mathbb{1}_{\{i=I\}} \left( \left(1 + \frac{\lambda}{1-(1+\lambda)^{-1/m}}\right) V_{i,0}^{n+1} - \frac{\lambda}{1-(1+\lambda)^{-1/m}} V_{i-1,0}^{n+1} \right)
\end{aligned}$$
